

OPERATION INSTRUCTION  
OF  
HAMMER HITTING TYPE BRINELL HARDNESS TESTER  
MODEL HBC

ISO9001

LAIZHOU HUAYIN TESTING INSTRUMENT CO., LTD.  
SHANDONG LAIZHOU TESTING MACHINE FACTORY

## **1. General Description**

HBC Hammer - Hitting Type Brinell Hardness Tester is designed to determine the Brinell hardness value of different metals by measuring the diameter of the indentations left on the testpiece and the standard hardness test block. The indentations are obtained in such a way that a steel ball of a certain diameter is put in between the testpiece and the standard hardness test block and then an instant impact load is applied onto them. The Brinell hardness value is thus obtained by first measuring the indentations and then referring to the conversion table attached.

This tester is especially suitable for the technician to use in workshops or material store houses due to its salient characteristics of simple construction, easy operation and convenience to carry.

This tester can approximately and rapidly measure the Brinell hardness of ferrous and non-ferrous metals as listed in this manual only.

## **2. Application**

- (1) Brinell hardness test of crude or annealed steel (of non-austenitic steel only).

- (2) Brinell hardness test of refinedly quenched or quenched and then tempered steel (of non-austenitic steel only).
- (3) Brinell hardness test of cast iron.
- (4) Brinell hardness test of brass casting.
- (5) Brinell hardness test of rolled brass.
- (6) Brinell hardness test of rolled copper.
- (7) Brinell hardness test of the alloy of tin and bronze.
- (8) Brinell hardness test of the casting of aluminium alloy.

Prior to the measurement, put the shaped end of the standard hardness test block in between the steel ball and the indentor (see Fig. 1), i. e. to let the spring inside the shell press the test block on to the steel ball tightly.

The rust or corrosion layer on the surface of the testpiece, if any, should be removed for a clear indentation so as to get a more accurate test result.

Having done the above, the test can be started. When doing the test, the hardness tester with

test block in must be first placed perpendicularly on the testpiece and then give a perpendicular and an instantaneous hit on the indentor with the hammer attached (The hit is not necessarily very heavy, see Fig. 2). Due to the hit by the hammer, an indentation is left at the same time on the standard hardness test block and the testpiece respectively. The diameter of the indentation on the standard hardness test block must not be beyond 4.2mm. If otherwise, the test is ineffective. When hitting the indentor, attention must be concentrated, not to hit second time on the same indentation.

The two indentations left on both the standard hardness test block and the testpiece should be measured by the attached 20 $\times$  microscope (the graduation of the knuckle wheel is 0.01mm). If the indentation is oval, the average diameter should be used. Besides, the center distance between the two adjacent indentations on the standard hardness

Fig. 1

test block must not be less than 10 mm.

When the measurement of the indentations is taken (the third decimal be rounded or interpolated), you can look up from the attached conversion table the hardness value of the testpiece.

Finally, the user's attention is invited that after long service of the tester, the convex shaped end of the indentor will be deformed because of the frequent hitting by the hammer. In such a case, the indentor must be perfectly dressed before it is used again.

Instruction for how to use the conversion table:

First refer to the table which is for the material that you want to test, from which first find out the caption column "The Diameter of the indentation on the standard hardness test block" and

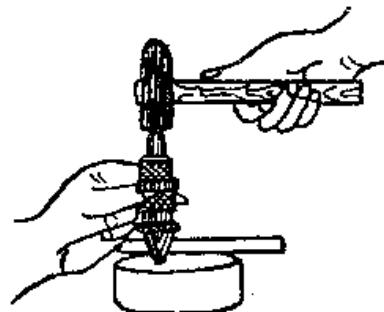

Fig. 2

consequently decide the transversal column according to the practically measured diameter of the indentation. Then find out the caption column "The diameter of the indentation on the testpiece" and consequently decide the longitudinal column according to the practically measured diameter of the indentation. And then extend the two columns to where they focus. And just here in the focused lattice you can get the wanted Brinell hardness value.

Example:

When the test is to be done by using the standard hardness test block, the hardness of which is 197HBS.

(Suppose the testpiece is of crude or annealed steel)

And as it is known: The diameter of the indentation left by the steel ball on the standard hardness test block is 2.3mm.

The diameter of the indentation left by the steel ball on the testpiece is 2.5mm.

Then: the Brinell hardness value looked up = 150 HBS. (from Table 1)

Thus: the Brinell hardness value of the testpiece =  $150 \times$  proportional coefficient (here it is 1)

In this operation manual are included several digit tables, from which you can look up the Brinell value of the material that you want to test.

The digits given in the table are all based on the standard hardness test block, of which the Brinell hardness is 197 HBS. All the standard hardness test blocks attached to this tester are imprinted at the end with its actual Brinell hardness value and the proportional coefficient to be used in conversion. Therefore, if the hardness value of the attached hardness test block is greater or less than 197 HBS, the Brinell hardness value looked up from the conversion table must be multiplied by the proportional coefficient imprinted on the test block used. The result is the Brinell hardness of the testpiece.

Example:

If the Brinell hardness value of the standard hardness test block is 185HBS.

Its proportional coefficient is 0.94.

So the Brinell hardness test value =  $0.94 \times$  Brinell hardness value.

One more example:

If the Brinell hardness value of the standard hardness test block is 217HBS.

Its proportional coefficient is 1.10.

So the Brinell hardness test value =  $1.10 \times$  Brinell hardness value.

The others by analogy.

Table 1 – Brinell Hardness Test Value of Crude or Annealed Steel

Remarks for Table 1:

- 1 The table is suitable for non-austenitic steel only as the figures covered in the table refer to nothing about austenitic steel.
2. The heat treatment condition of the tested material should be better known. If otherwise, the table is only suitable for those materials of  $HB < 360$ .

**Remarks:**

1. The Brinell hardness test value in this table is measured under such conditions that the load applied is 9807N, the diameter of the steel ball is 10mm, and the thickness of the testpiece is greater than 6mm.
2. The figures in the table only stand for the Brinell hardness test value of the castings of aluminium alloy.
